theories due to Fisher on the one hand, and to Neyman and Pearson on the other, are quite distinct. This is reflected in the fact that separate terms are often used (although somewhat inconsistently) to designate the two approaches: Significance testing for Fisher's and Hypothesis testing for that of Neyman and Pearson.* But are they really that different? It is interesting to see what Fisher, Neyman, and Pearson themselves have to say

Neyman and Pearson proposed 20% ($\beta = 0.20$) as an upper ceiling for beta, and the value of alpha ($\beta = \alpha$) as its lower floor (Neyman, 1953). For symmetry with the main hypothesis, the alternative hypothesis can, thus, be written so as for

The Neyman-Pearson lemma is quite useful in electronics engineering, namely in the design and use of radar systems, digital communication systems, and in signal processing systems. In radar systems, the Neyman-Pearson lemma is used in first setting the rate of missed detections to a desired (low) level, and then minimizing the rate of false ...

Neyman-Pearson hypothesis testing contributed strongly to decision theory which is very heavily used (in statistical quality control for example). Hypothesis testing readily generalized to accept prior probabilities which gave it a Bayesian flavor.

Classical statistical theory—hypothesis testing, estimation, and the design of experiments and sample surveys—is mainly the creation of two men: Ronald A. Fisher (1890-1962) and Jerzy Neyman (1894-1981).

The mathematical theory of statistical inference was mainly developed by Ronald A. Fisher, Jerzy Neyman, and Egon S. Pearson. Fisher on the one side and Neyman-Pearson on the other were involved often in a polemic controversy. The common view is that Neyman and Pearson made Fisher's account more stringent mathematically.

The hybrids of Fisher's and Neyman-Pearson's theory are briefly addressed. The lack of random sampling and its consequences for statistical inference are also highlighted, leading to the recommendation to dispense with inferences and perform approximate randomization tests instead.

...A distinction frequently made between the approaches of Fisher and Neyman-Pearson is that in the latter the test is carried out at a fixed level, whereas the principal outcome of the former is the statement of a p value that may or may not be followed by a pronouncement concerning significance of the result [p.1243].

The Neyman-Pearson theory of hypothesis testing, with the Type I error rate, α , as the significance level, is widely regarded as statistical testing orthodoxy. Fisher's model of significance testing, where the evidential p value denotes the level of significance, nevertheless dominates statistical testing practice.

Fisher was a prominent Eugenicist, and he had six children in accordance with his belief that the path to improvement of the human race involved increasing the propagation of superior specimens of humanity. A central question for us is: "Is modern statistics FREE of its Eugenicist origins?". The minority position is NO.

Randomization in this context never gets you a better test than what you would have without randomization. With discrete distributions, the distribution of the p-value, assuming the null hypothesis is true, is a discrete distribution, so for example, it may be that for one value of the test statistic, the p-value is \$0.07\$ and for another it is \$0.04\$. In that case, one could

Under different data assumptions, the minimizing argument of the ROC functional is shown to be the point of an ROC manifold corresponding to the Neyman-Pearson criteria. A second functional, the l_2 norm, is shown to determine the min-max threshold. A more robust functional is developed from the offered functionals.
