In all ultrasound-guided paravertebral block techniques, an indication of correct needle tip placement is the anterior displacement of the parietal pleura when the solution of local anaesthetic is being injected.

Ultrasound-Guided Paravertebral Block

An ultrasound-guided technique has the potential to reduce complications by providing direct visualization of the paravertebral space during needle manipulation. We evaluated the complications using a single-injection, transverse, in-plane ultrasound-guided technique for paravertebral blockade in patients undergoing mastectomy with immediate reconstruction for breast cancer treatment or prophylaxis.

Continuous thoracic paravertebral block for analgesia in patients with rib fractures has been reported. 1-4 More recently, ultrasound-guided thoracic paravertebral block has been suggested for greater precision over surface landmarks. 5, 6 In our report, we discuss the use of continuous thoracic paravertebral block for analgesia to facilitate hospital discharge in a patient with multilevel unilateral rib fractures.

Ultrasound-Guided Continuous Thoracic Paravertebral Block ...

Thoracic paravertebral block is the technique by which local anaesthetic is injected in wedge shaped paravertebral space alongside of the vertebral body called the thoracic paravertebral space (TPVS). This provides unilateral somatic and sympathetic blockade at selective segmental regions.

Thoracic paravertebral blocks (TPVBs) provide an effective pain relief modality in conditions where thoracic epidurals are contraindicated. Historically, TPVBs were placed relying solely on the landmark-based technique, but the availability of ultrasound imaging makes it a valuable and practical tool during the placement of these blocks.
