The interaction between system and surroundings is realized via quantities, which are called input and output. Quite often one wants, through a proper choice of the input, the system to behave in a certain way. Mathematical Systems Theory is concerned with the study and control of input/output phenomena.

The interaction between system and surroundings is realized via quantities, which are called input and output. Quite often one wants, through a proper choice of the input, the system to behave in a certain way. Mathematical Systems Theory is concerned with the study and control of input/output phenomena. The emphasis is on the dynamic behaviour of these phenomena: how do characteristic features change in time and what are the relationships?

Uwe's interest in the intersection between mathematical system theory on one side and certain topics in physics, systems biology or electrical engineering on the other side has always been driven by his deep belief that system theory can always contribute something new, possibly better, and maybe even more efficient, if correctly applied.

An operation is commutative if the order in which the elements are combined does not change the result. $a * b = b * a$. Associative property. An operation is associative if, when combining the elements, the grouping of the elements does not change the result. $(a * b) * c = a * (b * c)$ Distributive property.

Dynamical systems theory is an area of mathematics used to describe the behavior of the complex dynamical systems, usually by employing differential equations or difference equations. When differential equations are employed, the theory is called continuous dynamical systems. From a physical point of view, continuous dynamical systems is a generalization of classical mechanics, a generalization where the equations of motion are postulated directly and are not constrained to be Euler ...
